

Section I. Introduction

I have given a general account of the work relating to the ~~other~~ survey during the jute and aus paddy season in a separate Report, in which I have described the progress of the survey during the earlier part of the year. It would be remembered that I had originally submitted a joint scheme for the survey of crops in both the aus and aman paddy seasons but sanction was given by the Government of Bengal in the first instance to proceed with the work on only the jute and aus crops. We therefore started preparatory work in February 1944 on the basis of only the jute and the aus crops. After further discussions with Mr. J.N.Talukdar (~~who~~
acting as Secretary, Agricultural Department in April 1943) and subsequently with Mr. Hill who succeeded him we also started in May 1943 preparatory work for a survey of the aman crop but this had to be discontinued towards the end of June under instructions from Mr. Hill as the Agricultural Department did not consider it desirable to proceed with the scheme. This sudden change in the plan naturally dislocated the whole of the preparatory work.

2. At that time we were passing through an unprecedented food crisis in the province. In view of the importance of ascertaining the correct position in regard to the supply of rice I approached the Honorable Mr. H.S. Suhrawardy, Minister in charge of Civil Supplies and placed my views before him. I was informed unofficially in July and formally in August that Mr. Suhrawardy had decided to take up the survey of the aman crop from the Department of the Civil Supplies. This gave us the opportunity for the first time of making a comprehensive survey of the paddy crop in Bengal. Unfortunately by this time the season was well advanced and the field operation of the area survey in the jute-aus season had already terminated over the greater part of the province. A good portion of the field staff had in consequence been disbanded. Immediate steps were however taken to re-organise the programme of work etc were taken in hand. There was not time, however to get ready a fresh design for the survey of the aman crop and we decided to adopt the design which we had already used during the Jute-Aus season. Certain extensions were however made to cover areas in which the Jute and Aus crops were not important but in which Aman paddy was largely sown.

Section 2. Field Organization.

5. The general structure of the organization was similar to that used in the survey in the jute-mus season but important changes were made for improving the efficiency of the primary work. The whole province was divided into 22 blocks as in the jute-mus season. The total time available for the field survey being much smaller we however used 52 field units (each consisting of four or five investigators, and one special investigator in charge of one inspector) in the place of 42 units employed in the jute-mus season. The posts of Check Inspectors were abolished and were replaced by 14 posts of Chief Inspectors; posts of camp investigators were also abolished. One Chief Inspector was placed in charge in each of the 22 blocks and had two or three field units under him. At a convenient place within each Block a camp office was opened where the inspectors could keep the maps and records in charge of a camp clerk.

4. The field staff was organized into two broad parties (A) and (B), and arrangements were made to do the area enumeration work independently by each of these two parties. Each block was divided into a number of sub-blocks the total number of such sub-blocks being 360. Only one set of maps being available for field work, the programme was arranged in such a way that the two parties (A) and (B) could be supplied with maps required for their work at the propertime.

5. The field staff consisted of one Supervisor, two Assistant Supervisors, 21 Chief Inspectors, (Inspector being in charge of one Block, the only exception being the Calcutta block which was kept under the direct control of the Head Office), 50 Inspectors, 272 Investigators, and 25 camp clerks. The ~~maxim~~ actual number of men employed was of course much greater as shown in the following Table (1) in which col. (1) gives the designation of the workers; col. (2) the cadre or nominal strength; col. (3) the actual number of persons employed at one time or other. The number of persons who resigned, were discharged, or were given casual appointments are shown in cols. (4), (5) and (6) respectively. The total number of days of leave is given in col. (9); and with and without pay are shown in cols. (7) and (8) respectively.

Table (1) : Field Staff in Survey of Aman Paddy 194 -44.

Designation	CABRE	Number of Persons					Number of days of leave,		
		Actually appointed	Resig- ned	Dischar- ged	Casual appointment	With Pay	Without Pay	Total	
(4)	(5)	(6)	(7)	(8)	(9)	(10)			
Chief Inspectors	22	22	-	1	1	64	17	81	
Inspectors	50	61	6	2	11	48	93	147	
Investigators	272	306	29	41	116	218	180	507	
Camp Clerks	25	50	1	2	5	34	37	91	
Total	368	501	38	46	153	364	462	826	

6. It will be noticed that no less than 501 persons were employed in the course of about three or four months to fill 368 posts, also that nearly 30 man-months were lost on account of leave.

Progress of Area Survey

7. The area survey of aman paddy began in different Blocks on different dates between 15th and 15th September. Work in Block No.19 was completed on the 11th November while the survey in Block Nos.5 and 20 continued till 20th December. The distribution of the area survey work is shown by Blocks Table (2) in which col.(1) gives the serial number of the blocks; col.(2) gives the names of districts; col.(3) the actual duration of survey; col.(4) the number of field camps (i.e., places where the field staff stayed at night); col.(5) the number of field units; col.(6) the number of investigators; and col.(7) the number of pay-days of investigators. The no. of number of grids (each of size 2.25 acre) originally allotted to each Block is shown in col.(8) and the number actually enumerated in col.(9); out of these the number checked by Inspectors is shown in col.(10). It will be noticed that the number of grids originally allotted was 70,773; this was intentionally made high so as to enable the quicker workers to give some scope for doing a larger volume of work. The total number actually enumerated was 62,441 out of which 6240 or almost exactly 10 per cent were checked by the inspectors; it shows this number of sp. civil check parties went round and checked 376 grids.

Table (2) : Distribution of area Survey work by Blocks in Aman Season 1943-44.

Name of Districts	Period of Survey.	Number of camps.	Number of Units.	Inves- tiga- tion.	Pay days.	Allot- ed.	Kamura ation.	Number of grids.	Checked by Inspect ion.
(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)

Midnapur	21/9-15/12	7	3	11	1030	3552	3159	238	
Total	15/9-20/12	574	50	401	20455	70773	62451	6240	

8. In 1943 the field survey had to be carried out in the midst of an unprecedented food crisis in the province. The workers had sometimes to pay at the rate of Rs. 40/- or 50/- per mauna of rice even at this price supply was often not available and some of the workers had to go without a solid meal a day from time to time. We approached the Government of Bengal for obtaining rice at controlled rates for our workers but there was great delay in issuing necessary order.

9. Many of the workers left us on account of illness or due to securing employment on better terms elsewhere. A number had to be discharged for unsatisfactory work. The number of casualties due to resignation or discharge are shown in col.(4) and (5) of Table (1) respectively the total number of casual appointments for short periods are also shown by categories in col.(6).

10. One great difficulty was the high rate of incidence of Malaria. This was aggravated by the fact that in spite of repeated efforts we were unable to obtain a supply of quinine from Government for our workers. We were told that the field workers should apply to district authorities for quinine. It is scarcely necessary to point out that this procedure was altogether impracticable. The investigators are supposed to move about from one village to another and may become ill at any odd place and it is altogether impossible for them to obtain a supply of quinine from district authorities at the actual time of illness. As we were unable to supply quinine we had no other alternative but to give the worker leave during the period of illness. Details are given in cols.(7),(8) and (9) of Table (1). It will be noticed in this way we lost 826 working days altogether, that is, something of the order of 40,000 months. It is obvious that a far more economical policy would be to supply quinine and other medicines, at our expense. I hope better arrangements in this regard would be made in future.

Crop cutting work

11. For crop cutting now a different organization of field units was used. The Chief Inspector with his camp clerk and two special investigators form a one unit, and such unit worked in 4 localities within each Block. Each unit halted in one locality for one week and cut the crop on plots which were selected at random in the Statistical Laboratory in accordance with a definite plan. At the time of crop cutting also the field staff also made some area enumeration for the grain crop which the plots for crop cutting had been selected. Besides the special crop cutting units in charge of Chief Inspectors described above, Inspectors also did some crop cutting work as soon as the area survey was finished. Each Inspector selected three of the Investigators under him and proceeded with the crop cutting work on broadly the same plan as the Chief Inspector's units, but the Inspector's unit usually worked in only one centre.

12. The distribution of crop cutting work by Blocks is shown in Table (2) in which the first two cols. give the serial number of the blocks

blocks and names of the districts; col.(3) the period of crop cutting work; col.(4) the number of camps or localities visited in each party block; col.(5) the number of plots in which crop cutting work was done, and col.(6) the number of pay-days of investigators used for this purpose. Two different sizes of cuts were used, namely, 6' x 6' and 12' x 12' and the number of cuts of each size secured in each block is shown in cols.(7) and (8) respectively. It will be noticed that there were altogether 6,480 cuts of size 6' x 6' and 3072 cuts of size 12' x 12'.

Eye estimation Test

16. As in the Jute-mus season arrangements were made to hold examinations in 12 different centres in December 1843 to test the proficiency of workers in making eye estimates of the yield per acre of paddy. It is gratifying to report that no less than 146 candidates appeared at the examinations on payment of one rupee each as entry fee among whom 25 were awarded prizes ranging from 5/- to 100/-. The results of the test are discussed in a later section, but it may be mentioned here that the experiment was successful in every way. A number of candidates were found to possess exceptional ability in making reliable eye estimates of the yield per acre. Secondly, the competition aroused a good deal of interest and must have indirectly improved the quality of crop cutting work by inducing the field staff to give themselves good training in eye estimation work by weighing the harvested crop with accuracy in the course of their ordinary field work.

Design of the Survey

As already mentioned, sanction for the census survey was given very late when no time was left for thorough revision of the programme. The design used in the case of the survey of main paddy was similar to that during the jute-mus season. Certain modifications were however introduced at the last moment. As already mentioned, 15 additional sub-blocks were included in the survey to cover regions in which jute and other crops were not important but in which main paddy was grown in appreciable quantities.

15. The work in 1942 had been carried on under great difficulties and it had been found that the quality of the field work had deteriorated somewhat. It was thought it desirable therefore to strengthen the statistical controls. The principle of sub-sampling, that is, a curing the field area in the form of two independent inter-penetrating half-samples (by two different parties (A) and (B) of the field organization) was retained, but arrangements were made to have some of the grids actually enumerated in duplicate by both the field parties. This made it impossible to adhere to the uni-stage technique, and we decided to use a three-stage sampling. In the first stage, 50 per cent of the police stations or sub-blocks within each block were selected at random; within each selected sub-block a certain number of sheets of C.S. village maps were then selected at random; and finally, in each such selected sheet a number of grids of size 2.25 acre were located at random. Arrangements were made to have the work done by both parties in 67 per cent of the sub-blocks against 66 per cent in the jute-mus season; in the same way the number of sheets on which work was done by both parties was increased from 30 to 37 per cent; and finally, the proportion of grids enumerated in duplicate was increased from 16 to 37 per cent.

16. It would be seen therefore that there was a very appreciable strengthening of the statistical controls. The duplication of sample units does not however, supply any additional information and the fact that 37 per cent of the grids (in 37 per cent of selected sheets) had to be enumerated in duplicate meant at least 7 per cent of additional field work and 50 per cent of additional computational work up to the stage of inspection. All this was of course unproductive, but this was the price we had to pay to guard against undue unreliability of the primary work. It was thought it desirable to be on the safe side in view of the great importance of the question in a year of acute food crisis.

17. For convenience of reference we shall call any sub-block or sheet in which enumeration work is done in duplicate by both the parties (A) and (B) or any grid which is enumerated in duplicate be "duplicated" sub-block sheet or grid respectively; other sub-blocks sheets or grids would be called "single". The distribution of sub-blocks, sheets and grids of both "duplicated" and "single" types is shown by districts in Table (4) in which col.(1) gives the name of the district; cols.(2), (3) and (4) the number of duplicated, single and the total number of sub-blocks respectively. In the same way cols.(5), (6) and (7) give the number of duplicated and single and the total number of sheets respectively included in the survey; and cols. (8), (9) and (10) give the duplicated, single and total number of grids respectively. Finally, including the duplicated grids col.(11) shows the total number of grid enumerations; thus the total number of grids enumerated being 45,536 out of which 16,835 were having been duplicated there were 62,431 enumerations of grids altogether.

18. As the chief purpose of duplicating the work was to test the reliability of the primary enumeration, care was taken to camouflage the duplication by partial overlapping of the duplicated units within duplicated or single ones. This was maintained at all three stages so that the field staff had no knowledge as to which sub-blocks, or which sheets, or which grids were going to be duplicated. This made it next very difficult if not impossible for duplicate records being prepared by copying.

Preparatory Work

19. As soon as unofficial information was received at the end of July 1947 that Government had decided to proceed with the survey of urban parity, arrangements were made to resume the preparatory work which had been suspended in the third week of June. The break had however seriously dislocated arrangements in the Laboratory, and it was some time before the work could be brought up to full strength. However, by placing every available man on the job the preparatory work was finished in time to enable the field survey being started on the 10th September. This was possible only because of the ungrudging work on the part of the old guards of the Statistical Laboratory.

20. Two sets of khasra or crop record forms (showing the revenue plot number and the area in acre of each plot falling within the grid) were prepared and supplied to the field staff for being filled in with the annual estimate of the area under different crops. This involved listing the plot number and area of about 13 lakhs of plots. Additional copies were also required for the field as well as for computational work in the Statistical Laboratory. We therefore used two pieces of carbon papers for curing the necessary number of carbon copies; and in this way 18,000 sheets of carbon papers had to be consumed for this work alone.

21. In order to prevent any breakdown due to the loss of field records in transit under our conditions, arrangements were made for one set of field records to be sent to Calcutta and the other to the Giridih Branch of the Laboratory directly from the field. Advantage was taken of this arrangement to proceed with primary tabulation independently in Calcutta and at Giridih. This gave us a 100 per cent control ~~and~~ at the stage of compilation as it was a simple matter to compare certain fixed figures as reported by the two branches of the Laboratory in Calcutta and at Giridih.

22. Progressive Tabulation: Arrangements ~~were~~ were made for proceeding with the tabulation work in the form of accumulated totals so that progressive estimates of the area under aman paddy were prepared at the end of every week. The rpm proportion of land under crop obtained from individual grids were then plotted in a two-way chart in which the x-axis showed the dates and the y-axis the intervals of crop-proportion in fine classes. The forecast of the crop under aman paddy each week was obtained by direct summation of the results over seven days, and was also checked by obtaining the frequency distribution over the whole week and then calculating the mean value.

Section 4. Area under Aman Paddy

23. In this Section we shall discuss the material relating to the area survey of Aman paddy in 1943-44.

Sub-sample estimates

24. As already mentioned in the earlier section the sample survey covered 341 sub-blocks out of which 220 were surveyed in duplicate by (A) and (B) parties. In the duplicated sub-samples not all but only a certain number of C.S. village sheets were common to both the parties and within each duplicated sheet only two grids out of a total of four were enumerated by both the parties. The two estimates for the area under aman paddy based on the work done by the two parties (A) and (B) on the same set of "duplicated" sub-blocks selected at random were thus associated. The agreement between these two estimates would therefore supply a good idea of the reliability of the primary field work. In the non-duplicated or single sub-blocks the work was done by one party, and the estimate based on such single sub-blocks furnished a third value which we have called the 'C' sub-sample. This third estimate was of course independent of the pair of associated sub-samples 'A' and 'B'.

25. All three estimates 'A', 'B' and 'C' are given by districts in Table (5) in which col.(1) gives the name of the district, col.(2) the total geographical area in thousand acres; col.(3) the number of duplicated sub-blocks and, col.(4) gives the number of sheets of C.S. village maps in which work was done by both the parties; col.(5) the number of duplicated grids which were enumerated by both parties (A) and (B). The estimated area under aman paddy in thousand acres together with the standard error of the estimate based on the work done by party (A) is shown in col.(6); and the percentage variability (meeting thereby the standard error of the estimate expressed as a percentage of the estimate itself) is shown in col.(7). The corresponding estimated area together with its standard error based on the work of party (B) is given in col.(8) with the percentage variability in col.(9). The number of single (or non-duplicated) sub-block sheets and grids are shown in cols.(10), (11) and (12) respectively. The third or (C) sub-sample estimate of the area together with the standard error is given in col.(13); and the corresponding percentage variability in col.(14). This combined area estimate

estimate is shown in Table (6) in which the figures in cols.(1) - (7) are arranged in exactly the same way as in Table (5).

26. For a statistical comparison of the three different estimates (A), (B) and (C) we have used Fisher's t-statistics which is simply the difference of the two estimates under comparison divided by the standard error of the difference. (Large sample theory can be used in this comparison because the number of grids employed was large in every case). The values of Fisher's 't' for the 3 different comparison (A-B), (A-C) and (B-C) are shown in Table (6) in the cols.(6), (8) and (10) respectively. It will be noticed that with a few exceptions the values of 't' are less than two. The agreement between the 3 sub-samples (A), (B) and (C) were thus fairly satisfactory although conditions were not completely under control. The agreement was not too close and thus does not suggest any appreciable use of the same set of records having been copied by the both parties.

27. It will be noticed from the figures given in the bottom line of Table (5) that the (A), (B) and (C) estimates for the province as a whole were 28,240 and 247 lakhs of acres, the pooled value being 244 lakhs of acres of land sown with aman paddy.

28. The standard error of the estimates was calculated in each case on the basis of multi-stage formulae. The relevant material for this purpose is shown in Tables (2), (8) and (9) respectively. In each of these tables col.(1) gives the name of the district; col.(2) the degrees of freedom and col.(3) the variance between grids within sub-blocks; in the same way col.(4) shows the degrees of freedom and col.(5) the ratio of the variance between sub-blocks to variance within sub-blocks ~~not between grids~~. Finally, the estimates of the variance of the stage-means between sub-blocks and between grids within sub-blocks are given in the last two cols.(6) and (7) respectively. These are purely technical constants which are being given here for convenience of future reference but need not be further discussed here.

29. One or two comments may, however, be made on the percentage variability of the estimated area under aman paddy shown in cols.(7), (9) and (14) of Table (5) and in col.(7) of Table (6). These supply a standard measure of the percentage margin of error of the results. For the province as a whole these are usually of the order of 2 or 3 per cent.

indicating that the estimates are not likely to be out by more than 5 or 6 per cent once in 20 trials. Values for individual districts are naturally much larger and fluctuate widely from district to district.

30. It would be remembered that the primary field records are given in the form of area estimates of the proportion of land under aman paddy in each plot falling within the grid. Multiplying these area estimates by the corresponding area of the plot we get the actual area of land under aman paddy in each plot; and adding up these areas we get the total area (or proportion) of land under aman paddy in each individual grid. In any region, say, within a given block or district we can form a frequency distribution of the proportion of land under individual grid, and it is clear that such a frequency distribution will be characteristic of the district under consideration. In the sample survey we have material for calculating the proportion of land under aman paddy within individual grids enumerated. For this we can form the frequency distribution of grid-proportions within different blocks. The frequency distribution of grid-proportions for each block is shown in Table (10).

31. One point is worth noting in Table(10). The most frequent value almost invariably occurs at the $p = 1$ or full proportion which shows that aman paddy is most often seen over the whole of the plot. The next largest frequency occurs at the zero value, which shows that in the case of aman paddy the tendency is either zero to leave the plot out altogether. Between these two limits, the frequency distribution is more or less uniform.

Progressive Estimates of the Area Under Aus and Aman Paddy

32. It has been already mentioned that tabulation was done in the form of accumulated totals which made it possible to prepare progressive estimates are given in Table (11) in which col.(1) gives the chronological or serial number of the week beginning from the last week of May; col.(2) the actual period of field work in calendar dates; col.(3) the number of sub-blocks included in the tabulation. The proportion of land under aus paddy is given in col.(4), and the corresponding proportion under aman paddy in col.(5) while the proportion of land under both aus and aman paddy is shown in col.(6).

33. Aus Paddy: It will be noticed that the proportion of land under aus paddy is high at the end of May, but falls to something like a steady value between 9th June and 8th July and then decreases somewhat but is still quite high at the end of August. In September the proportion rapidly decreases and becomes practically nil by the time winter survey starts. The high intensity of cultivation in the earlier part of the survey may have been partly due to the fact that the field work was done in the comparatively rich aus districts during the earlier weeks. It is possible that broadcast aus (which is sown earlier in the season) is more easily distinguished from aus paddy than transplanted aus. If this is true then there would be less chance of transfer from aus to aus paddy in earlier weeks, but such transfers would increase as the season advances and more and more transplanted aus begin to come under survey.

34. Amun Paddy: Estimate of the proportion of land under amun paddy is available from very beginning of the summer survey in May till the middle of November. It decreased from 31 per cent at the end of May to 19 per cent in the third week of June after which it steadily increased to the maximum value of 71 per cent in third week of September after which it gradually decreased and was more or less steady at about 55 or 54 per cent in October or November.

35. The progressive estimates are shown separately for the different districts in Tables (12), (13) and (14) which give an interesting picture of the position in different regions and show the time at which the area was most fully sown with amun paddy in different parts of the province.

Area Survey at the time of Harvesting

36. Arrangements were made for the crop-cutting units to make an area survey at the time of doing their crop-cutting work. These units worked in 120 centres distributed at random all over the province. Within each centre a number of sheets were selected at random out of the 100 sheets which had been used during the main area survey; and the grids already used for the area survey were again used for crop-cutting work. Each worker was instructed to enter the area estimate of the plots falling within the grids allotted to him even if the crops were not available for being harvested in any of the plots.

37. In this way a supplementary area survey was made during the actual harvesting period by a selected group of workers. The estimates are shown in Table (15) in which col.(1) gives the name of the district; col.(2) the geographical area of the district in thousand acres; col.(3) the number of sub-blocks; col.(4) the number of sheets, and col.(5) the number of grids covered during the main area survey and col.(6) the area under sown in thousand acres together with the corresponding standard error based on the pre-harvest survey. In the same way col.(7) gives the number of sub-blocks; col.(8) the number of sheets, and col.(9) the number of grids covered during the area survey carried out at the time of harvesting, and col.(10) the estimated area together with the standard error based on this survey. In the two districts of Hooghly and Howrah the crop-cutting work was done along with the intensive programme of similar work in connection with the Burwan-Hooghly-Howrah Flushing and Irrigation Scheme, and no area survey was done at the time of harvesting. The values shown within brackets are therefore calculated values obtained from the ratio of the provincial totals for cols.(6) and (10) of Table (15).

38. It will be noticed that the area under sown paddy at the time of harvest was 212.55 ± 6.75 lakhs of acre against a pre-harvest estimate of 244.46 ± 3.75 lakhs of acres. The acreage at the time of harvest was thus appreciably lower. Owing to the failure of the rains or insect blights or destruction by animals or other causes the harvested area must be less than the sown area. The observed difference is therefore in the right direction but as the estimate of the area at harvesting time is based only on about 4,000 grids in 119 sub-blocks it is not possible to draw any definite conclusions.

Section 5. Crop Cutting Work on Aman Raddy : 1943-44

39. As already mentioned, crop-cutting work on aman paddy started on the 19th November and was continued till early January 1944 in some of the districts. The work was done by 22 units each consisting of two or three investigators under one Chief Inspector who secured sample cuts in 120 centres distributed at random all over the province. In each locality 15 sample units were located on sheets at densities ~~and~~ one in one, one in two and one in three in a balanced design. Each selected sample sheet was divided into four quadrants, and in each quadrant two grids were located at random and the worker was asked to collect two cuts, one of size 6' x 6' and the other of 12' x 12', in each of two plots contained within the grid.

40. As already mentioned, each worker also recorded the area estimate of the proportion of the land under aman paddy in each grid allotted to him even if crops on all the plots were not available for being harvested. This served a dual purpose. Firstly, it supplied an independent estimate of the area under aman paddy at harvest time. Secondly, this enables the rate of total production per sample sheet being directly calculated by multiplying the rate of yield (y) by the intensity or proportion of land under cultivation (p). Taking the average of these supply these products (which we may write as yp) supply directly an estimate of the rate of production per unit of geographical area, while the average of different values of y (which we may write as \bar{y}) gives the rate of yield per unit of cropped area. An alternative method for estimating the total production is by multiplying this average rate of yield (\bar{y}) by the average intensity or proportion of land under cultivation (\bar{p}). This method ignores the mutual correlation which might exist between the intensity of cultivation (p) and the rate of yield (y). The method of calculating the total production by taking the average value of the joint product (yp) is therefore definitely an improvement in the method of estimation.

41. Before considering the total production of rice it is necessary to mention certain disconcerting features in the crop-cutting work. As already mentioned, cuts of two different sizes namely, 12' x 12' and 6' x 6' were obtained from each plot. Relevant data are given in Table (16) in which col. (1) gives the serial number of the field unit;

col. (2) the number of villages covered by each field unit during crop-cutting work; cols. (3) and (4) the mean yield in tolas per sq. foot of freshly harvested paddy based on cuts of size 12' x 12' as collected in samples (A) and (B) respectively. In the same way cols. (5) and (6) show the mean yield in tolas per sq. feet based on cuts of size 6' x 6' in samples (A) and (B) respectively. It will be noticed that the mean yield based on cuts of size 6' x 6' for the province as a whole was 21.89 and 21.56 respectively for (A) and (B) samples. Against these figures we have mean yields of 16.86 and 16.09 based on corresponding cuts of size 12' x 12'.

42. In the same Table (16), col. (7) shows the number of cases in which the yield based on 12' x 12' cuts was in excess (by more than +5 tolas) of the corresponding yield based on cut of size 6' x 6' located in the same plot; col. (8) shows the number of cases in which the difference was between +5 and -5 tolas; and finally, col. (9) the number of plots in which the yield based on 6' x 6' cut was higher than the corresponding yield based on the 12' x 12' cut by more than 5 tolas.

43. It would be remembered that cuts of both the sizes 6' x 6' were obtained from each of the plots. Mean yields based on the two sizes of cuts would not, of course, be identical but would differ by chance fluctuations. It is obvious however that, unless there is any bias, the number of occasions on which the rate of yield would be higher for the smaller cuts of size 6' x 6' would be roughly the same as the number of occasions when the yield would be lower for the smaller cuts. A glance at cols. (7), (8) and (9) of Table (16) shows that this is far from true. In fact we find that in 622 plots the rate of yield was greater for cuts of smaller size as against 233 cases in the rate of yield was greater for cuts of larger size. This shows that there was a tendency to overestimate the rate of yield in the case of cuts of the smaller size. This may be due to some of the bordering plants having been drawn within the cuts. Such a border bias, if any, would naturally be of greater importance in the case of cuts of smaller size. Observed bias may also be due to the an unconscious tendency selecting high yielding patches which possibly could be seen easily in the case of the smaller size of cuts.

44. It will be noticed that the material falls into broadly two groups. In the case of certain field units such as Nos.(1), (4), (6), (7), (9), (17), (20), and (22) there is on the whole no marked bias; but in the case of the remaining field units the number of negative differences are much larger. It is also remarkable that it is just these field units which show a strong bias that the agreement between the two subsamples (A) and (B) is usually closer. This also is suspicious.

45. It is of course not possible to state definitely just what had happened. In our previous studies on the jute crop and also to a smaller extent on the paddy crop we had found that there was a definite tendency to overestimate the rate of yield when the size of the cut was very small. We found however that in the case of jute, cuts of size bigger than, about $4' \times 4'$ were practically free of bias. However, in the view of the possibility of the yield based on the smaller size cuts having been overestimated we have rejected the records for the $4' \times 6'$ cuts and made all subsequent calculations on the basis of the records for $12' \times 12'$ cuts.

Yield of Aman Rice

46. The yield of rice (not in husk) in maunds per acre of cropped area based on sample-cuts of size $12' \times 12'$ is shown for each district in Table (17) in which cols. (1) and (2) give as usual the name and geographical area in thousand acres of the districts; cols. (3) — (5) show the coverage of the crop-cutting work in different districts in terms of number of sub-blocks, sheets, mauzas and cuts of size $12' \times 12'$. The calculated rate of yield of Aman rice (not in husk) in maunds per cropped acre is shown in col. (6). (The figures for the two districts Hooghly and Howrah have been obtained from the crop-cutting work in the Burdwan-Hooghly-Howrah Flushing and Irrigation Scheme). Multiplying these rates of yield by the estimated area during the pre-harvest survey shown in col.(6) of Table (15) or by the estimated area at the time of harvesting shown in col. (10) of Table (15) we get two alternative estimates of the total yield of rice (not in husk) in thousands of maunds given respectively in cols. (7) and (8) of Table (17). On the whole it appears safer to adopt the estimated figure of 25.59 crores of maunds for the province as a whole as shown at the bottom of col. (8).

Alternative Methods of Calculating total Production

47. It is also possible to calculate the total production by using the rate of yield (y) and the proportion of land under man power in each sheet (p). By multiplying these two we get the rate of total production per sheet or per acre of geographical area. Estimates based on this method have the great advantage of enabling the standard errors being calculated by straightforward methods. Relevant figures are given in Table (18) in which col. (1) and (2) give the name and total geographic area of the district in thousand acres; col.(3) the estimated area under man power in thousand acres to; together with the corresponding standard error, and col.(4) the percentage variability (which is simply the standard error of the estimate area expressed as a percentage of the estimated area itself). In the same way, the rate of yield of rice (not in husk) in maunds per acre together with the standard error is shown in col.(5) and the percentage variability in col.(6). Finally the total production of rice obtained by first calculating the average value of the joint product (yp) and then multiplying this by the total area of the district is shown in col.(7) together with the standard error, and the percentage variability of the estimated total production in col.(8). It would be noticed that by this method the total production comes out as 26.64 \pm 4.93 crores of maunds.

48. The standard errors have been calculated by appropriate multi-stage formulae. It would be noticed that for the province as a whole the estimated area has a standard error of 3.56 per cent; the mean rate of yield a standard error of 2.4 per cent, and finally the estimated total production has a standard error of 3.74 per cent. The margin of error for individual districts is naturally much higher.

49. We find that on the basis of the available material the estimated total production of Ann rice (not in husk) in Heng 1 in 1943-44 comes out at 25.30, 26.45 or 26.64 crores of maunds depending on the method of calculation. We also find that calculated standard error is 3.74 per cent, or say of the order of four per cent. We may, therefore, reasonably conclude that the total production of Ann rice probably lies somewhere between say 23.4 and 28.6 crores of maunds.

Section 6. General Discussion of the Results

50. It may be mentioned here that the sample estimate of the pre-harvest or seeded area is 244 lakhs or nearly 36 per cent higher than the official figures of about 180 lakhs of acre. The sample estimate of the harvested area is 212.55 lakhs of acre which also is about 18 per cent in excess of the official estimate. As this is the first year of the sample survey, no direct evidence is available to enable us to settle the matter this way or that. We, however, possess some indirect evidence. It is known that the work done during revisional Settlement operations in Bengal is on the whole quite reliable. We therefore attempted a comparison between the area under aman paddy as given in the Settlement Reports with the contemporaneous official figures. The material is shown in Table(19) in which col.(1) gives the name of the district; col.(2) the geographical area; and col.(3) the years of Settlement operations; col.(4) the area under Aman paddy as given in the Settlement reports; and col.(5) the average value of the area under Aman paddy as given in the official Season and Crop Reports for the years mentioned in col.(3). The successive official estimates are also given for the years 1934 - 1945 in the succeeding cols.(6) - (15).

51. It will be noticed that the official estimates were usually smaller than the corresponding Settlement figures. In fact the total area according to official estimates was only 144.58 lakhs of acre against a total Settlement figure of 192.16 lakhs of acre. The official estimates have thus to be increased by no less than one third. (or 33 per cent) in order to reach the Settlement figure.

52. A far more important point is that according to Settlement operations the total area under Aman paddy was not less than 192.16 lakhs of acres. In view of the unprecedented rise in prices in 1945 it is almost certain that the area sown with aman paddy in 1945-46 would be something greater than this. On this view of the matter the estimates obtained from the sample survey appear to be far more plausible than the official estimate.

55. We find that the sample estimate of the acreage under aman paddy at the time of harvesting was 16 per cent in excess of the official figure. We have already seen that the standard error of the area under aman paddy as estimated by the sample survey is 5.56 per cent. This shows that the internal agreement between the different subsamples was on the whole fairly satisfactory. An external comparison with the settlement records shows that the official figures are usually serious under-estimates. In this situation the sample estimate appears to be quite plausible. The margin of error is however large, and the sample estimate may differ from the true value by something like 8 or 9 per cent.

54. It would be remembered that the estimated production of Aus rice (not in husk) was given as 7.70 crores of maunds. We have also seen that a plausible figure for the total production of Aman rice (not in husk) in Bengal in 1943-44 is 23.4 prores of maunds. Adding these two it appears likely that the total production of Aus and Aman rice (not in husk) in Bengal in 1943-44 was something of the order of 31 crores of maunds with a possible margin of error of say 7 or 8 per cent. This is as far as we can go in regard to the production of rice in Bengal in 1943-44 on the basis of available evidence.

Section 7. Incidence and Effect of manuring on the Yield
of Aman Paddy : 1943-44.

55. At the time of the survey of aman paddy information was collected regarding the extent of the application of manures. This furnished material for studying how far manures were being used for aman paddy and what effect these had on the yield of the crop. Table (20) shows the extent of the use of manures; col.(1) gives the name of the district, col.(2) the number of plots which were manured and col.(3) the number of plots which were not manured; the total number of plots covered in the tabulation is shown in col.(4). The percentages of plots manured and not manured are shown in cols.(5) and (6). It would be seen that manuring was on the whole quite usual in districts Backergunj, Fazza, Jossore, Khulna, Nadia, Pabna, Faridpur and 24-Parganas. On the other hand, the practice was practically neglected in districts Birbhum, Burdwan, Bankura and Midnapore. The primary material shows that cowdung is practically the only form of manure that is being used in the province; manure in the present report therefore means cowdung alone.

56. Information was also collected as to the amount of cowdung used per bigha, but these are often only rough guesses reported in a casual manner by the cultivators. In fact in many cases it was difficult to find out whether the total quantity of manure reported to have been applied referred to only the particular plot under investigation or all the plots cultivated by the owner.

57. In spite of the rather unsatisfactory nature of the preliminary material we have made an attempt to study the effect of manuring on the rate of yield. Relevant figures are given in Table (21) in which the mean rate of yield of Aman paddy in maunds per acre in plots receiving different quantities of manure have been shown by districts. Under each district the column headed "N" gives the number of plots for which information was available and the second column, the yield. It will be noticed that the quantity of cowdung used varied widely from 1 maund to 150 m per bigha.

58. It must be remembered that the comparison which we are making here gives only a kind of overall average. In the case of unmanured plots we have no information what could have been the yield if manure had been used on the same plot. In the same way, we have records of yields of paddy in manured plots but have no knowledge as to how much less the yield would have been if no manure had been used at all. The comparison is thus not quite valid, as it is quite possible that the intrinsic fertility of the manured and unmanured plots were different. For example, suppose only the least fertile plots were manured, then the increase noticed would not give the total effect of manuring. On the other hand, suppose only the most fertile plots were manured then a great deal of the observed increase might be due to greater intrinsic fertility rather than to the manure. But looking at the figures given at the bottom of the table for the province as a whole it is interesting to observe that there is clear evidence of an increase in the rate of yield of paddy due to manuring. For example, in unmanured plots the overall provincial average yield was 16.58 maunds of rice (not in husk) per acre for all districts combined. The average rate of yield is higher and about 17.34 maunds per acre in plots receiving from 1 to 10 maunds of cowdung, and about 17.38 maunds in plots receiving from 11 to 20 maunds. There is an appreciable rise in the average yield to 18.35 maunds per acre on land receiving from 21 to 30 maunds of cowdung per bigha. There is further rise to 19.87 maunds per acre of land receiving from 31 to 50 maunds of cowdung per bigha. After this there is no further rise suggesting that there is probably not such additional gain in yield beyond the application of say from 1 to 50 maunds of cowdung per bigha.

59. The material is neither extensive nor reliable enough to bear more detailed analysis. It is however that the use of from 30 to 50 maunds per bigha on the whole increases the yield of rice (not in husk) per acre to 19.87 maunds from an average yield of 16.58 maunds in unmanured plots. There is thus a gain of about .35 maunds per bigha on an average due to the use of from 31 to 50 maunds of cowdung per bigha.

Section (8). Eye estimation of the Yield of Aman Paddy.

60. Various experiments have been made in different parts of the world regarding the possibility of making reliable eye estimates of the yield of crops. Several years ago a good deal of work in connexion with wheat was done in England which gave promising results. During Prof. R.A. Fisher's visit to India in 1937-38 I had the opportunity of discussing the question with him. In fact in a memorandum submitted to Lord Linlithgow (then Viceroy of India) Prof. Fisher suggested that experiments on eye estimation might be taken up in India at an early date. We did some work on the subject in a tentative way on the jute crop in 1940. I wanted to make a systematic effort in 1941 but was prevented from doing this on account of my own ill health. In 1942 I again gave instructions for eye estimation work being done on the jute crop but unfortunately owing to unforeseen difficulties and the not unnatural reluctance on the part of the supervising staff in the Field Branch no tangible progress was made. However in 1943 I decided to make a definite effort to explore the possibilities of eye estimation; and, as already mentioned in the introductory section, the results have been extremely promising.

61. Both in the Jute-aus as well as in the aman seasons I decided to offer prizes ranging from Rs.5 to 100 for proficiency in making eye estimates of the yield of jute and paddy. In the aman season examinations were arranged at 12 centres under the direct supervision of Field Supervisors and Statisticians and other senior workers sent out from The Statistical Laboratory. At each centre the examiners (who were usually two or three in number) went round and made ready a number of sample-units of the proper size bounded by ropes for being harvested. Before the crop was cut each candidate was required to make an eye estimate of the yield in terms of maunds of rice (not in husk) per bigha, and these estimates were recorded in an answer book. In this way each candidate was required to make an eye estimate of the yield of from 15 to 20 cuts. After all the candidates had actually written down their own eye estimates, the crop on each of the plots was harvested and weighed in the presence of the examiners.

62. At each centre we thus had the weight of crop for each plot as actually measured by the examiners, and corresponding to each such weight we also had a number of values obtained by eye estimate by the different candidates. A specimen sheet of such results is shown in Table (22) in which actual records for a number of prize-winning candidates at Naogaon, Tarakeswar, Singur and Santiniketan are given in terms of mounds of rice (not in husk) per bigha. Col.(1) simply gives the serial number of the sample-unit at each centre. Under Naogaon we then have the different eye-estimates of the yield in mounds per bigha as given by worker Nos. 1, 2, 3, up to 9. This is followed by column headed "All" which gives the mean value of the yield based over the eye estimates of all 9 candidates; finally in the column headed "Actual" the yield as determined by direct weighing by the examiners themselves is given for each sample-unit. At the bottom of the mean value is given of all sample-units for each candidate separately and also for the two columns headed "All" and "Actual". At Naogaon we find that the mean yield for all 15 sample-units was 5.20 mounds per bigha. We also notice that the mean value of the eye estimates made by candidate No.1 was 5.25 by candidate No. was 5.80, by candidate No.3 was 5.20 mounds and so on. A glance at the figures would show that some of the candidates were thus highly successful in giving reliable eye estimates of yield. There were however large differences between the candidates. For example, Naogaon candidate No.9 had a mean yield of 6.98 mounds per bigha again on actual value of 5.45 mounds.

63. The results were scrutinised and analysed in various ways. Agreement of mean values was certainly one criterion. But this was not sufficient. For example we found that there were candidates who consistently under-estimated or over-estimated but whose eye estimate values were more or less uniformly proportional to the actual values. It is clear that in such cases if the candidates could correct their bias they could be able to make extremely reliable eye estimates. This suggested using the correlation between the eye estimates and the actual values as second criterion. A candidate having a high correlation of his eye estimates with the actual values may be considered to be a more promising candidate than one having a low correlation. There was also a third factor. A candidate may guess very widely of the mark and yet by chance

chance cancellation of values largely in excess or in deficit may reach a mean value near that of the actual value. It is clear that the standard deviation of the errors would throw some light on the ability of the candidates. As between two candidates having roughly the same mean values, the one with lower standard difference would be obviously more promising.

64. It is not necessary to enter into technical details but I may mention here that all these factors were taken into consideration in awarding the prizes. In the Asian season out of 148 candidates 25 were considered deserving of receiving prizes. It was also found that some of the top men had very good aptitude in making correct eye estimates of the yield.

65. Let us just consider for a moment the possibilities of the method. Our experiment shows that we had among our own staff men who could make eye estimates with a high degree of reliability. We found that the mean value based on 20 eye estimate often agreed with the actual value within 2 or 3 per cent. The work takes very little time. All one would have to do is to go round with a map and identify a number of plots selected at random in a village or within a group of villages and make a note of the yield of each such plot by eye estimation. One investigator would in this way be easily able to collect say from 30 to 40 eye estimated values in a group of villages. As already mentioned, we have reasons to believe that the mean value based on such a number of eye estimate would not probably differ from the actual value by more than two or three or say five per cent at the most when the work was done by competent men. Any such investigator moving from place to place would be able to make several hundred of eye estimates in the course of a month.

66. The work done this year therefore deserves being continued in future. The method appears to be extremely promising. But a good deal of further studies must be made before it can be standardized. Suitable men must be found and given necessary training. Finally there is the all important question of honesty. The fact that man is able to make good

good eye estimates does not mean that he would always do so in practice. It is clear therefore that it would not be possible to rely exclusively on eye estimation. Personally I believe that the ~~xxxx~~ most promising line of advance would be to us, both eye estimation and the method of actual objective crop-cutting work in combination. Each would then act as a check on the other. Careful control experiments must be made regarding the type of organization, but given a little time and necessary facilities I feel confident that evolving a sound technique would merely be a matter of a little patient experimentation.

Section 9. Uncultivable waste and Fallow Lands.

87. During the survey of the main crop information was collected about the proportion of land lying fallow in all the 330 sub-blocks ~~xxviii~~ covered in the survey. A certain portion of this material picked up at random has been tabulated and the results are given in Table (23) in which col.(1) gives the name of the district, col.(2) the total geographical area in thousands of acres; cols.(3) and (4) the number of police stations covered in the survey by the two field parties (A) and (B) respectively. The estimated area of culturable waste in thousands of acre based on the work done by the (A) and (B) parties are shown separately in cols.(5) and (6); and the pooled estimated values in ~~xxxix~~ col.(7). In the same way estimated values of current fallow land in thousand acres are given in cols.(8) and (9) respectively for material collected by the two parties (A) and (B) and for the pooled material in col.(10). Finally the total area of culturable waste land or current fallow is shown by two parties (A) and (B) in cols.(11) and (12) respectively; and the pooled values in col.(13).

88. It appears from Table (23) that in the whole of Bengal about 88.3 lakhs of acres were either lying as current fallow or were culturable waste land in 1945-46.

89. For purpose of comparison we are showing Settlement and official estimates of current fallow and culturable waste in Table (24); col.(1) gives the name of the district and col.(2) the year during which settlement operations were made in each district. Estimates of the culturable waste ~~immeasurable~~ other than current fallow as given in settlement reports are shown in col.(3) and the area not available for cultivation in col.(4); and finally the total area of current fallow in col.(5); the total of these three items is given in col.(6).

90. The corresponding figures abstracted from the official publication in the "Area and Yield of the Principal Crops in India in 1937-38" is shown in cols.(7) to (9). The area of culturable waste land other than current fallow has been shown in col.(7); the area not available for cultivation in col.(8) and the area of current fallow in col.(9) and finally the total of the items in cols.(7) to (9); is shown in col.(10).

91. It will be noticed that there are many discrepancies between the figures given in Settlement reports and those given in official publication on "Area and Yield of Principal Crops in India in 1937-38" and naturally between these two and the sample estimates. All we can say is that the sample values are of the right order. It is only after the sample survey has been repeated for 3 or 4 years that the real position can become known.

Table (2). Distribution of Crop-cutting work in 1941-42.

Block No.	Name of Districts.	Period of work	Number of Crop cutting Plots Day			Number of plots Cult. C.R. 10% 100	
			(1)	(2)	(3)	(4)	(5)
1	Santipur, Jharsuguda	20/11 - 20/12	6	240	181	623	163
2	Puri, Bhadrak, Kendrapara	27/11 - 18/12	5	212	152	333	153
3	Jajpur	19/11 - 10/12	6	184	143	384	152
4	Gajapati, Nayagarh, Khurda	6/12 - 25/12	6	237	243	633	153
5	Boudh	24/11 - 25/12	6	322	173	434	152
6	Mahendragiri, Jajpur	1/12 - 27/12	6	414	206	603	152
7	Dhenkanal, Deogarh	28/11 - 11/12	6	344	276	534	154
