

STATISTICAL NOTE ON CROP-CUTTING EXPERIMENTS ON PADDY
IN HYDENSINGH 1939-40.

General Form of the Tables.

1. The serial number given in column (0.1) is for use for reference in the Statistical Laboratory. The next column (0.2) gives the J.L.No.; column (0.5) the name of Thana, Union or Mouza; and column (0.4) the serial number of samples which are actually harvested in the case of Mauzas.
2. The main results are given in the three columns (1), (2), and (3) for ek-fasali, do-fasali and all-fasali respectively. Columns (1.1), (2.1) and (3.1) give the number of half-samples (each consisting of four sub-samples or cuts), and columns (1.2)^(2.2) and (3.2) the number of cuts actually harvested. The mean yield of paddy together with a range on either side equal to the standard error (i.e. the standard deviation) of the mean is given in maunds per acre in columns (1.3), (2.3) and (3.3) respectively.
3. It will be noticed that instead of probable errors I have used the standard error of the mean as this is more usual in current statistics. In terms of probability this implies that odds are 2 to 1 that the true mean lies within the given range. The tolerance range can if desired, be easily increased to the 5 per cent level by using twice the standard error, that is, by doubling the given range on either side. In this case the odds will be only 1 in 20 against the true mean lying within the range.
4. Two index numbers are given in the last two columns. Column (5.1) shows the do-fasali yield as a percentage of the ek-fasali; and column (5.2) the dry weight of paddy as a percentage of the green weight. It has not been possible to complete the work for dry weight for all the thanas at the time of writing this Note. Results for one thana (Nalitabari) are being sent herewith, the results for all the four thanas will follow in the course of a few days. I may note however that the dry weight percentage is very steady; and may be taken as 87 per cent without any appreciable risk of error.

5. The form is practically the same as the one sent by Mr. Bastin with his covering letter of the 1st March 1940. For convenience of statistical work we have given the number of samples and cuts instead of the area cut; the latter information can be easily obtained by multiplying the number of cuts by a constant multiplier 27.04 sq.feet (neglecting very slight variations due to the whole of a cut not being under paddy). For economy of space we have omitted the total cutturn of green paddy as this also can be easily obtained from the maximum number of cuts and the mean yield per acre. It will be seen, therefore, that the information given here is practically the same as in Mr. Bastin's form.

Thana and Union Summaries

6. Tables (1) and (2) give a summary of the information in a condensed form for the Thanas and Unions respectively. Supplementary information regarding "percentages of total cuts" are also given in these cases. It will be noticed that a great deal of paddy had been harvested before the field work was started; and the actual number of half-samples (each consisting of four cuts) collected was 4340 which was only about 16 per cent of the total number laid out in the maps. As the paddy on 36 per cent of other samples had been already harvested it will be seen that 54 per cent of the total samples were under paddy; 14 per cent were under other crops; 31 per cent were uncultivated while no records were available for about 1 per cent of samples.

7. The over-all mean yield for all five thanas was 23.2 ± 0.2 maunds per acre for ek-fasali, 15.5 ± 0.4 maunds per acre for do-fasali, and 22.2 ± 0.2 maunds per acre for all-fasali. These appear to be quite reasonable estimates for the season. The variation between Thanans were not large but were statistically significant in some cases. Thus for ek-fasali Halitabari had the highest mean yield (25.2 ± 0.3 maunds per acre); Durgapur (22.9 ± 0.2), Haluaghata (22.6 ± 0.3), and Kalmakanda (21.8 ± 0.5) formed a middle group with roughly the same yield; and Sribardi came last with 20.6 ± 0.5 maunds per acre. The differences between Unions were also statistically significant in many cases showing the existence of local differences in yield.

8. The information for each Mauza (classified under Unions) is given in Table 3. Besides the usual information we are also giving certain adjusted values of the mean yield in maunds per acre in the case of mauzas in columns (4.1) and (4.2) for ek-fasali and all-fasali respectively. These adjusted mean values were obtained in the following way. The observed mean yields together with the corresponding ranges in terms of standard deviations (which are given in ~~maunds~~ columns (1.3) and (3.3) were plotted on thema maps. Smooth lines of equal yield (at intervals of three maunds per acre on either side of 25) were then drawn by inspection. These lines of equal yield together with the yields in surrounding mauzas were carefully scrutinized, and adjusted values (lying within the adopted tolerance range) were written down as reasonable estimates for the mauzas. The procedure is certainly subject to some extent; but doubtful cases were considered by two or three statistical workers independently, and the final values were adjusted after discussion with me. These adjusted values may be of some use in actual work of assessment especially in the case of mauzas in which no samples are available. It is scarcely necessary for me to emphasize that the adjusted values must be used with great caution and discretion as they are not based on actual observations, but on what is at best a reasonable graduation of the available material.

9. In some mauzas it has not been possible however to give any adjusted values as there was no basis for making any estimates. In such cases the mean yield of the Union will supply some information.

10. I should like to add a few words of caution from the statistical point of view. Owing to early harvesting only about 16 per cent of the total samples could be collected while paddy was actually grown on about 54 per cent of total samples. This means that we succeeded in obtaining less than 30 per cent of ~~individual~~ ~~samples~~ ~~from~~ ~~the~~ ~~total~~ ~~possible~~ samples. This has appreciably reduced the number of samples available for individual mauzas; and has consequently increased the margin of error. This has also meant that a large number of mauzas were left complete blanks which is even more serious than the reduction in the size of the sample in individual mauzas.

11. Another important point is the question of seasonal fluctuations. From a study of the frequency distribution I am of opinion that the present estimate for each thema as a whole may be considered to be reasonably accurate for the 1939-40 season. We have, however, no information how far these estimates are representative of different seasons; from a statistical point of view it is therefore risky to accept the mean yields in one season as the standard basis for assessment.

Statistical Report on the Crop-cutting Experiments on the
Paddy in Mymensingh : 1939-40.

Section 1. Introduction, Yield of Green Paddy and study of Variance.

Introduction

A Crop-cutting experiment on Aman paddy only was carried out in 1939-40 in the Mymensingh District under the general direction and supervision of Mr. Bastin, Settlement Officer, Mymensingh. The main object of the experiment was to determine the average yield per acre of Aman Paddy for purpose of assessment of land revenue. The preliminary report on the yield of paddy by mauzas, unions, and thanas, was submitted on the 6th May 1940. Supplementary information relating to the yield of straw, and various statistical constants relating to paddy are given here. These will be of great help in preparing plans for future surveys of this type.

2. The statistical plan for the scheme was prepared in the Statistical Laboratory. The area surveyed comprised five Thanas (Durgapur, Haluaghat, Almalkanda, Malitabari, and Shribardi) covering 837 square miles. It was divided into 14 halkas, approximately of 60 square miles, each under a Kamungo. Each Kamungo had 6 mins working under his supervision, so that each min was required to complete the crop-cutting work in ten square miles in the season. A Senior Revenue Officer, stationed at P.S. Malitabari, supervised the field work of the 7 ~~main~~ eastern halkas Nos. 5, 6, 7, 8, 9, 10, 11; and another Senior Revenue Officer, stationed at Durgapur, supervised the work of the 7 western halkas Nos. 1, 2, 3, 4, 12, 13, 14. The forms and schedules for field work as also instructions of investigators were supplied from the Statistical Laboratory, Calcutta.

3. It was decided to take 16 samples per square mile to leave a margin for unforeseen wastage. Each sample consisted of two half-samples, each having 4 cuts (each of area 25.04 sq.ft.) situated on apposite corners of a square. The samples were located at random in the Statistical Laboratory, and their position marked on the 16 mauza maps, which were then supplied to the halkas - Kamungos.

4. Many of the samples fell on uncultigated land, tanks, homesteads, etc., or on land not growing paddy or growing paddy or growing unripe paddy; and a great deal of paddy had been harvested before the actual commencement of the field work. In most cases it was found that of the two half-samples constituting a sample, only one could be - collected. The actual number of half-samples (each consisting of our tufts) gathered was 4340 which was approximately 16 per cent of the total number laid out in the maps. As paddy on 38 per cent of other samples had been already harvested, it will be seen that 54 per cent of the total number of samples were actually under paddy, although we could obtain only less than 30 per cent of the possible samples on account of the delay in starting the field work. Of the rest, 14 per cent were under other crops, 31 per cent were uncultivated while no records were available for about 1 per cent of the samples.

5. The paddy from each cut of a half-sample was threshed separately and the weights of green paddy and straw were entered in the field book. One of the cuts in a half-sample was reserved for dry weighing of paddy and straw. Besides the jurisdiction List Number of the village and the Revenue Number of the plot from which the sample was collected, the following entries were recorded in the field book:-

- (1) Class of land
- (2) Nature of cultivation
- (3) Date of taking green weight
- (4) Date of taking dry weight
- (5) Name of variety of paddy
- (6) Green weight of paddy
- (7) Green weight of straw
- (8) Dry weight of paddy
- (9) Dry weight of straw
- (10) Weight of Chitta
- (11) Area under unripe paddy
- (12) Area under paddy already harvested
- (13) Area under nutan patit
- (14) Area under other crops
- (15) Area of other lands
- (16) Area under Ail

Records were also kept as to the class of land i.e. ek-fasali (single-cropped) or do-fasali (double-cropped); there were only four instances of tri-fasali (triple-cropped) land which were neglected in the analysis. Detailed instructions were also given to each kanungo to inspect the work of each amin under him at least on alternate days, and the Senior Revenue Officers were required to make surprise inspection of the work of kanungos.

Yield of Green Paddy

6. The detailed results for the yield of green paddy were shown in Table 1 which was sent with a Preliminary Report on the 6th May, 1940. The mean yield of green paddy for all the thanas taken together was found to be 23.2 ± 0.2 maunds per acre for ek-fasali, 15.5 ± 0.4 maunds per acre for do-fasali, and 22.2 ± 0.2 maunds per acre for all-fasali. The variations in mean yields between Police Stations were not large, although statistically significant in some cases. The percentage of dry weight to green weight was found to be very steady, being roughly 87 percent on an average for the five Thanas.

7. The observed mean yields in individual mauzas for ek-fasali and all-fasali were plotted on thana maps, and iso-yield contours (lines of equal yield) were drawn at intervals of three maunds per acre. With the help of these contour lines adjusted figures were obtained for individual mauzas for ek-fasali and do-fasali crops. In the case of certain mauzas, however, it was not possible to give even these adjusted values for lack of samples in adjoining areas. The important question of seasonal fluctuation could not be considered and it would be hazardous to accept those estimates of the mean yields in one season as the standard yields.

Study of Variance : Weight of Green Paddy.

8. As mentioned above, the survey was carried out in five Police stations, viz. Durgapur, Haluaghata, Kalmakanda, Malitabary and Sribardi. For convenience of reference, we give below in Table (1.1) the number of unions, mauzas, half-samples and cuts collected in each of these police stations.

Table (1.1). Number of Half-samples and Cuts by Police Stations.

Police Stations	Unions	Mouzas	Half Samples	Cuts
Durgapur	11*	142	815	3090
Haluaghata	14	143	1187	4531
Kalmakanda	8	84	319	1174
Nalitabari	19	160	1200	4670
Sribardi	11	85	819	3126
	68	614	4340	16,591

9. The variation in yield can conveniently be studied by the analysis of variance for the weight of green paddy "between Thanas", "between Unions", "within Unions between Mauzas (J.L.'s)", and "within J.L.'s between half-samples". These similar results for each Thana separately are shown in Table (1.2). Variations "between Unions" and "within Unions between J.L.'s" are significant. The variations "between Thanas", "within Thanas between Unions", and "within Unions between J.L.'s" shown in Table (1.2) are also significant. This definitely established the existence of heterogeneity in the material.

10. We next proceed ~~now~~ to estimate the "basic" variances "between Unions" and "between J.L.'s" for each of the Police Stations. This is a case of three-fold nested sampling. Let V_1 be the observed variance "with J.L.'s between Samples", V_2 the observed variance "within Unions between J.L.'s" ~~which~~ and V_3 the observed variance "between Unions", values for which are given in Table (1.2). Further, let S^2_1 , S^2_2 and S^2_3 , be the estimates of the basic variance "between half samples between Mauzas" and "between Unions" respectively; and let 't' be the number of Unions, n_i the number of J.L.s within the i-th Union, and m_{ij} the number of samples within the j-th mauza in the i-th union, so that

$$\text{Total number of Mauzas} = \sum_i n_i = n \quad \dots \quad (1)$$

$$\text{Union} \quad \dots \quad (2)$$

$$\text{Total number of samples in } K_i \text{-th Union} = \sum_j m_{ij} = m_i \quad \dots \quad (3)$$

$$\text{Total number of samples} = \sum_i \sum_j m_{ij} = m \quad \dots \quad (4)$$

$$We \text{ have then : } \quad V_1 = S^2_1 \quad \dots \quad (4)$$

$$V_2 = \frac{m - \sum_i \frac{\sum_j m_{ij}^2}{m_i}}{n-t} \quad S^2_2 + S^2_1 \quad \dots \quad (5)$$

$$V_3 = \frac{m - \sum_i \frac{\sum_j m_{ij}^2}{m_i}}{t-1} \quad S^2_3 + \frac{\sum_i \frac{\sum_j m_{ij}^2 - \frac{1}{m} \sum_i \sum_j m_{ij}^2}{m_i}}{t-1} \quad S^2_2 + S^2_1 \quad \dots \quad (6)$$

11. Employing the above formulae it is easy to calculate the actual values of S_1 , S_2 and S_3 in the different cases. We have also obtained the values of S_4 the standard deviation corresponding to the total variance. For convenience of comparison, we have reduced the mean yields and standard deviations to maunds per acre in every case. The results are presented in Table (1.3), where col. (1) gives the name of the Police Station, and col. (2) the mean yield of green paddy in maunds per acre, cols. (3), (5), (7) and (9) give the degrees of freedom for variation "between Unions" (f_1) "within Unions between J.L.'s" (f_2), "within J.L.'s between Half-samples" (f_3) and total variation (f_4); whilst cols. (4), (6), (8) and (10) respectively give the corresponding standard deviations, and cols. (11), (12), (13) and (14) respectively the corresponding co-efficients of variation C_1 , C_2 , C_3 and C_4 .

12. The mean yield of Police Stations is quite steady, being of the order of 22 maunds per acre, except in Sribardi where it is low, and roughly 18 maunds per acre. The effect of this low yields noticeable in the co-efficients of variation for this Thana which are high in all cases. For the other Police Stations, the coefficient of variation "between Unions" fluctuates from 5.41 per cent in Nalitabari to 20.56 per cent in Kalmakanda and 21.47 per cent in Sribardi. This indicates that the Unions in Nalitabari and Durgapur were comparatively homogeneous but the Unions in the other three Police Stations, were definitely ~~most~~ heterogeneous. The coefficient of variation "between J.L.'s" varies from about 14 per cent in Durgap to nearly 25 per cent in Sribardi. The coefficient of variation "with J.L.'s between Half-samples" is quite steady being roughly of the order of 30 per cent in all Thanas except in Sribardi. Where it is 46 per cent. Finally, the total coefficient of variation also is very steady and about 39 per cent ; except in Sribardi where it is again as high as 56 per cent.

13. Examining the results within a Police Station it appears that the coefficient of variation progressively increases from "between unions" to "within Unions between J.L.'s", "within J.L.'s between Half-samples", and "total variation". This is exactly what we expect because the smaller the number of samples ~~maxx~~ the larger

inevitably will be the corresponding variance, and in the present case because the means are roughly of the same order, also the corresponding coefficients of variation.

14. We may discuss on similar lines the results of analysis of variance for all five Thanas taken together. This provides an example of a four-fold nested sampling. We use the same notation as before, denoting the observed variance "within J.L.'s between half-samples," "within Unions between J.L.'s", "within Thanas between Unions" and "between Thanas by V_1, V_2, V_3, V_4 respectively, and the estimates of the corresponding basic variances by S^2_1, S^2_2, S^2_3 and S^2_4 respectively. Further, let 'T' be the number of Police Stations, n_i the number of Unions in the i -th Police Station, m_{ij} the number of mauzas in the j -th Union of the i -th Police Station, and p_{ijk} the number of half-samples in the k -th mauza of the j -th Union of the i -th Police Station.

$$\text{Total number of Half-samples} = \sum_i \sum_j \sum_k p_{ijk} = p \quad \dots \dots \dots \quad (7)$$

$$\text{Number of Half-samples in } i\text{-th Thana} = \sum_j \sum_k p_{ijk} = p_i \quad \dots \dots \dots \quad (8)$$

Number of Half-samples in the j -th Union in

$$\text{the } i\text{-th Thana} = \sum_k p_{ijk} = p_{ij} \quad \dots \dots \dots \quad (9)$$

$$\text{Total number of mauzas} = \sum_i \sum_j m_{ij} = m \quad \dots \dots \dots \quad (10)$$

Total number of mauzas in the i -th

$$\text{Thana} = \sum_j m_{ij} = m_i \quad \dots \dots \dots \quad (11)$$

$$\text{Total number of Unions} = \sum_i n_i = n \quad \dots \dots \dots \quad (12)$$

We have the following expressions :-

$$V_1 = S_1^2 \quad \dots \dots \dots \quad (13)$$

$$V_2 = \frac{p - \sum_i \sum_j \frac{p_{ij}}{m_i}}{m - n} S_2^2 + S_1^2 \quad \dots \dots \dots \quad (14)$$

$$V_3 = \frac{p - \sum_i \frac{\sum_j p_{ij}}{n_i}}{n - t} S_3^2 + \frac{\sum_i \sum_j \sum_k \frac{p_{ijk}}{p_{ij}} - \sum_i \sum_k \frac{p_{ijk}}{p_i}}{n - t} S_2^2 + S_1^2 \quad \dots \dots \dots \quad (15)$$

$$V_4 = \frac{p - \sum_i \frac{p_i}{p}}{t - 1} S_4^2 + \frac{\sum_i \sum_j \frac{p_{ij}}{p_i} - \sum_i \sum_k \frac{p_{ijk}}{p}}{t - 1} S_3^2 + \frac{\sum_i \sum_k \frac{p_{ijk}}{p_i} - \sum_i \sum_j \frac{p_{ijk}}{p}}{t - 1} S_2^2 + S_1^2 \quad \dots \dots \dots \quad (16)$$

15. The calculated values of S_1 , S_2 , S_3 and S_4 together with the value of S_5 , the maximum standard deviation corresponding to total variance, in maunds per acre shown in Table (1.4) where col.(1) gives the mean yield, cols. (2), (4), (6), (8) and (10) the degrees of freedom "between Thanans", "within Thanans between Unions", "within Unions between J.L.'s", "within J.L.'s between Half-samples" and "Total variation" respectively; and cols. (3), (5), (7), (9) and (11) the estimates of the corresponding basic standard deviations. Finally cols. (12), (13), (14), (15) and (16) give the corresponding coefficients of variation symbolised by C_1 , C_2 , C_3 , C_4 and C_5 respectively, which come out to be roughly 11 per cent, 14 per cent, 20 per cent, 34 per cent and 42 per cent respectively.

Section 2. Varietal Difference.

16. The results have been analysed separately for the five important varieties of paddy, viz., Chapalani, Gaita, Chapali, Askal and Dhepa. Mean values and standard deviation with corresponding standard errors in maunds per acre for yield of green paddy for each Police Station separately and for all five Police Stations combined are presented in Tables (2.1)-(2.6); for dry paddy in Tanles (2.7) - (2.12); for green straw in Tables (2.13)- (2.18); for dry straw in Tables (2.19) - (2.24); and for chitta in Tables (2.25) - (2.30). All the tables are of precisely the same form, col. (1) giving the name of varieties, col. (2) the number of cuts, col. (3) the mean values with standard errors, col.(4) the standard deviations with standard errors and col.(5) the coefficients of variation with standard errors. Besides the results for individual varieties, these for the five varieties taken together for all varieties (only for dry cuts), and all cuts have also been recorded in each of the above tables. The coefficients of correlation between (1) green paddy and dry paddy, (ii) green paddy and green straw, (iii) dry paddy and dry straw and (iv) dry paddy and chitta are given in Tables (2.31), (2.32), (2.33) and (2.34) respectively. All these tables are of the same form, col.(1) giving the name of varieties; cols. (2.1), (3.1), (4.1), (5.1), (6.1) and (7.1) the number of dry cuts for Durgapur, Haluaghata, Kalmakanda, Nalitabari, Sribaridi and all Thanans respectively; and, finally, cols. (2.2), (3.2), (4.2), (5.2), (6.2) and (7.2) the values of the corresponding correlation coefficients.

In all the tables, values of the correlation coefficients not significant at the 5% level of probability have been enclosed within brackets.

17. The mean yield of green paddy is quite steady and of the order of 23 maunds per acre in the different Thanas except in Sribardi where it is 18 maunds per acre. On the whole "Chapalani" is a low-yielding variety with about 18 maunds per acre; Chapalani and Dhepa are medium-yielding varieties with roughly 22 maunds per acre; and Gaita and Askal are high-yielding varieties with about 26 maunds per acre. The results are very similar for the yield of dry paddy.

18. The mean yield of green straw is very low in Sribardi, being about 30 maunds per acre; and low in Halitabari, being 44 maunds per acre, the over-all average being 55 maunds per acre. In the other Police Stations, the yield is roughly of the order of 65 maunds per acre. As for the varieties, Chapali and Dhepa are low-yielding, with about 39 maunds per acre; Chapali is medium yielding with 51 maunds per acre; while Askal and Gaita are high-yielding, with yields of 63 and 75 maunds per acre respectively. The results for dry straw, naturally, are on the whole similar.

19. As for the mean yield of Chitta, the variation from Police Station to Police Station is not particularly marked. Chapalani and Chapali give low yields with about 0.76 maunds per acre; Dhepa gives medium yield with about 0.93 maunds per acre; and, finally, Askal and Gaita give high yields with about 1.12 maunds per acre. On the whole, therefore, taking into consideration all the five indices of yields, it would appear that Chapalani, Chapali and Dhepa are low or medium-yielding varieties, while Askal and Gaita are high-yielding, the latter definitely coming out as the best.

Coefficients of Variation.

20. As regards coefficients of variation it is obvious that low yields would result in high coefficients of variation and vice versa. For green and dry paddy we find that the over-all coefficients of variations are of roughly the same order, viz., 42 per cent. The coefficients of variation for individual varieties fluctuates considerably owing mainly to differences in mean yield. For green paddy it varies from 34 per cent for Gaita to 48 per cent for Dhepa; and for dry paddy from 35 per cent for Gaita to 53 per cent for Dhepa. The coefficients of variation for green straw and dry straw, are roughly of the same order, 67 per cent for all varieties taken together. For individual varieties the coefficient varies from 49 per cent for both dry and green straw; for Gaita to 80 per cent for Dhepa.

Coefficients of Correlation

21. The coefficients of correlation between the weights of green paddy and dry paddy are all highly significant, and of the same order in different police stations or for different varieties, being roughly + 0.94. It is, therefore, scarcely necessary to record the weights of both green and dry paddy.

22. The coefficients of correlation between the weights of green paddy and green straw are not as high as in the previous case, although all are significant except that for the variety Gaita in P.S. Malitabari. The value of the coefficient for the pooled material is 0.58. Variation in the value of the correlation coefficients from variety to variety is noticeable, that for Chapali and Askal over all thanas being roughly + 0.45 for Dhepa + 0.56, and for Gaita and Chapalani + 0.62 and + 0.68 respectively.

23. The coefficients of correlation between dry paddy and dry straw are roughly of the same order as those between green paddy and green straw, and all are significant except that for variety Gaita in P.S. Malitabari. The actual value for the whole material is + 0.56. As before, the different varieties are sufficiently marked. The value for Chapali and Askal over all thanas is roughly 0.45, for Dhepa 0.57 and for Gaita and Chapalani 0.53 and 0.71 respectively. The correlations between dry paddy and chitta is 0.43 & for the pooled material; and & there is only one non-significant value, viz., that for variety Gaita in P.S. Malitabari for which only a very small number of cuts were available.

Section 3. Frequency Distribution and percentage Frequencies for weight of Green paddy.

24. Frequency distributions were prepared of the number of (a) cuts, (b) half-samples, and (c) mauzas means falling within the class intervals of 0-5, 5-10, 10-15, 55-60 maunds per acre for the weight of green paddy for each Police Station as well as for all five police stations combined for ek-fasali, do-fasali and all-fasali crops. From these frequency distributions corresponding percentages were calculated. The frequency distribution for ek-fasali, do-fasali and all-fasali respectively for each Police Station separately and five Police Stations combined are presented in Tables (3.1), (3.3) and (3.5), and the corresponding percentage frequencies in Tables (3.2), (3.4), and (3.6). All the tables are of the same form, col. (1) giving the class-interval, cols.(2.1), (2.2) and (2.3)

the frequency distributions or percentage frequencies by cuts, half-samples and mauza means respectively for P.S. Durgapur; cols. (3.1), (3.2) and (3.3) the frequency distributions or percentage frequencies by cuts, half-samples and mauza means for P.S. Halumghat. In the same way cols. (4.1) (4.2) and (4.3) give the results for Kalamakanda; cols. (5.1), (5.2) and (5.3) for Malitabari; cols. (6.1), (6.2) and (6.3) for Sribardi; and finally, cols. (7.1), (7.2), and (7.3) for all thanas taken together. In Table (3.2), there are additional columns (2.4), (3.4), (4.4), (5.4), (6.4) and (7.4) showing the percentage frequencies derived from the iso-yield fertility contours. As some of the computations could not be completed, cols. (2.1), (3.1), (4.1), (5.1), (6.1) and (7.1) have been omitted in Tables (3.1), (3.2), (3.3) and (3.4).

25. It will be seen that percentage frequencies for cuts and half-samples are almost in complete agreement but are quite different from those for mauza means.

26. An attempt was made to calculate the proportion of land in each class by the method of two-yield contours. The observed mean yields in maunds per acre for mauzas along with a range equal to twice standard error with the mean as centre, were plotted on a thenamap. Smooth contours lines at intervals of 5 maunds per acre were then drawn on the maps; and in the case of mauzas for which samples were not available adjusted figures of yield were adopted on the basis of the contour lines. Then area between any two consecutive contour lines was measured by means of a planimeter; and all areas in a given class-interval were added to give the total area in square miles in each class interval. These were then converted into percentages. Unfortunately, owing to large gaps in the primary data the drawing of contour lines was to some extent liable to subjective errors which gave rise to considerable discrepancies between results obtained by different workers. It was, consequently, not considered profitable to carry on with this work beyond that for the ek-fasali yields, for which the mean results for each Police Station separately and all Police Stations combined have been given for purposes of comparison.

Green weight of Straw.

27. We have analysed the yield of straw in exactly the same manner as the green weight of paddy, the results for which have already been submitted. As before, the serial number of col.(0.1) is intended for use in the Statistical

Laboratory, Col. (0.2) gives the P.S.No., Union No. or J.L.No.; col.(0.3) the name of Police Station Union or Mauza; and col.(0.4) the serial number of samples which are cut in the case of table 4.1, and the serial number of samples which are actually harvested in the case of Table 4.3 cols.(1), (2) and (3) give the mean results for ek-fasali, do-fasali and all-fasali respectively. In cols. (1.1), (2.1) and (3.1) are given the number of half-samples (each consisting of four cuts), and in cols.(1.2), (2.2) and (3.2) the number of cuts actually harvested. The mean yield of green straw together with a range on either side equal to the standard error of the mean is given in maunds per acre in cols.(1.3), (2.3) and (3.3) respectively.

28. Finally, cols.(5.1) and (5.2) give the percentage of do-fasali to the ek-fasali yield, and the percentage of the dry weight of straw to its green weight respectively. It is of some interest to note that with the exception of P.S. Sribardi the percentage ratio of do-fasali to ek-fasali yield is roughly 60. Also the percentage of dry weight of straw to green weight varies from 50 in the case of P.S. Sribardi to 64 in the case of P.S. Kalmakanda, neglecting P.S. Durgapur for which the percentage attains the unusually high figure of 87.

29. Tables 4.3 give the information for each individual mauza⁶ classified union by union within each Thana.

30. Tables 4.1 and 4.2 give a summary of the information in a condensed form for the Police Stations and Unions respectively. The additional information regarding "Percentages of total cuts" has already been supplied with the results of analysis of green paddy.

31. The general mean yield for all the five police stations was found to be 56.5 ± 1.0 maunds per acre for ek-fasali, 31.1 ± 1.5 maunds per acre for do-fasali, and 52.9 ± 1.0 for all-fasali. It appears that there are fairly reasonable estimates for the season. For the police stations individually, the variation in the mean yield for ek-fasali was found to be considerable Sribardi giving mean yield of 37.7 ± 1.9 maunds per acre, Malitabari 47.5 ± 1.1 maunds per acre, Durgapur 59.1 ± 1.3 maunds per acre and Haluaghata 67.3 ± 1.1 maunds per acre. For do-fasali however, the variations between mean yields for police stations to police station, the lowest mean yield being Police stations were small and statistically negligible. For all-fasali, the mean yields were again very variable from police station to police station, the lowest mean yield being 34.1 ± 1.3 maunds per acre for Sribardi and the highest 66.1 ± 1.1 for Haluaghata.
